

Problem 5 (20 points)

A tank truck is used to haul a certain liquid. The truck has different masses depending on how full the tank is. The trucker is more concerned with the total mass of the truck and load than the mass of the liquid alone. Below is a graph of the mass of the loaded truck versus volume of liquid in the tank. The points represent the tank being one-quarter full, half-full, three-quarters full, and full.

a. What does the single point P tell you?

Student Solution:

P is the pt where the truck is at three quarters full. This means the total mass of truck is at 80,000 kg with a liquid of a volume of 75,000L

Dr. Saul: To receive full credit on part (a.), you needed to indicate that the coordinates of point P told you the mass of the truck + the liquid and the volume of the liquid in the truck and provide the values with units..

b. What is the density of the liquid when the truck is three-quarters full? Explain how you can tell.

There were two ways to find the answer to part b. One is realize that the Density of an object = the mass of the object / the volume of the object. Using point P,

$$D = \frac{\text{Mass of Liquid}}{\text{Volume of Liquid}} = \frac{M_{\text{truck+liquid}} - M_{\text{truck}}}{V_{\text{liquid}}}$$

$$\frac{80,000\text{kg} - 20,000\text{kg}}{75,000\text{l}} = \frac{60,000\text{kg}}{75,000\text{l}} = 0.80\text{kg/l}$$

(See part c on how to determine the mass of just the truck.)

Student Solution:

density = m/v The Mass of the truck is 20 (1000 kg)
 The Mass of the truck & 3/4 tank is 80 (1000kg). So the liquid itself has a mass of 60 (1000 kg)
 → Mass = 60 (1000 kg) / Volume = 75 (1000 liters)

Thus

$$\frac{60}{75} = \text{density}$$

$$0.8 \text{ kg/liter}$$

This is a good solution except for the tendency to leave the units off of numbers and not label the final answer.

The other way to do this problem is to realize after the initial point with volume = 0, the increase in mass in entirely due to the liquid. Thus the slope of the Mass vs. Volume line shown above is the density of the liquid. Picking the points where the truck is one quarter full of liquid and where the truck is full of liquid:

$$\text{slope} = \frac{\text{rise}}{\text{run}} = \frac{\Delta \text{Mass}}{\Delta \text{Volume}} = \frac{M_{\text{full}} - M_{\text{one quarter full}}}{V_{\text{full}} - V_{\text{one quarter full}}} = \frac{100,000\text{kg} - 40,000\text{kg}}{100,000\text{l} - 25,000\text{l}} = \frac{60,000\text{kg}}{75,000\text{l}} = 0.80\text{kg/l}$$

$$\text{density of liquid} = \text{slope} = 0.80 \text{ kg/l}$$

Problem 5 (cont.)

c. What is the mass of the empty truck? Explain how you found your answer.

Again, there are two ways to answer this question.

Student solution 1:

Thus, a full tank (4 quarters) of liquid has a mass of 80,000 kg.

Each quarter tank is 20 ~~kg~~ (1000 kg) $\xrightarrow{\uparrow}$

The total Mass w/a full tank is 100 (1000 kg)

Take away the 80 (1000 kg) of liquid & you are left
with 20 (1000 kg) which is the mass of the truck.

Student Solution 2: The line refers to the trendline through the points.

20,000 kg: continue the line until it reaches the y-axis. This
is the weight of the empty truck b/c the the volume is equal
to zero where the line touches the y axis

The point where the trend line crosses the vertical (y) axis is the y-intercept. This is the point where the truck is empty and volume and mass of the liquid is zero.
